Abstract

Robots are important tools in nuclear power plants since they could receive radiation without doing damage other than economy. It could be foreseen that once a material for robot fabricating that is radiation-resist enough, robot will be very universal in nuclear power plants. On the other hand, algorithms controlling the robot will be very important too. The complicated ground conditions in nuclear power plants require the robot to be able to climb stairs, avoid or step over various kinds of obstacles and make right decisions for saving energy.

Introduction

1.1 Literature review

1.2 Choice of technique

1.3 Projects to implement

Hopfield neutral space

2.1 Principles

2.2 Advantages and disadvantages

Algorithms to use for the two projects

3.1 Energy-saving path finding

3.2 Multi-arm robot

Optimizations of computer code

4.1 Vectorization

4.2 Numba and code modifications

Results and discussion

5.1 Energy-saving path finding

5.2 Multi-arm robot
